Abstract

We have performed multicanonical simulations of hydrophobic-hydrophilic heteropolymers with a simple effective, coarse-grained off-lattice model to study the structure and the topology of the energy surface. The multicanonical method samples the whole rugged energy landscape, in particular the low-energy part, and enables one to better understand the critical behaviors and visualize the folding pathways of the considered protein model.

Keywords: off-lattice protein models, Conformational Sampling, multicanonical Simulation.

I. INTRODUCTION

Predicting the proteins structure and the folding mechanism is an important goal in structural biology. Although the physical principles are known, the complexity of proteins as being macromolecules consisting of numerous atoms makes an accurate analysis of the folding process of realistic proteins extremely difficult. The configuration space of proteins presents a complex energy profile consisting of tremendous number of local minima, barriers and further topological features. Because of energy barriers, the commonly used thermodynamic simulation techniques are not very efficient in sampling of a rugged landscape. The simulated molecule often remains in its starting wide microstate or move to a neighboring wide microstate, but in practise it will hardly reach the most stable one. The system may be trapped in a basin for a long time, which results in nonergodic behavior. On the other hand, the topography of the energy landscape, especially near the global minimum is of particular importance; this is because the potential energy surface defines the behavior of the system. Consequently, a visualization of the whole rugged landscape, covering the entire energy and temperature ranges, would be helpful in developing methods to allow one to survey the distribution of structures in conformational space and also gives the details of the folding pathway. Such a goal can be achieved with the multicanonical approach.

The problem of protein folding entails the study of a nontrivial dynamics along pathways embedded in a rugged energy landscape. Therefore, one of the important aspects in this field is studying simple effective, coarse-grained models that allows a more global view on the relationship between the sequence of amino acid residues and the existence of a funnel-like structure along a pathway towards the energy minimum in a rugged free-energy landscape [1].

One of the most known examples is the HP model of lattice proteins, which has been exhaustively investigated [2, 3]. In this model, only two types of monomers are considered, with hydrophobic (H) and polar (P) character. Chains on the lattice are self-avoiding to account for the excluded volume. The only explicit interaction is between non-adjacent but next-neighbored hydrophobic monomers. This interaction of hydrophobic contacts is attractive to force the formation of a compact hydrophobic core which is screened from the (hypothetic) aqueous environment by the polar residues. Statistical mechanics aspects of this model are being subject of recent studies [4, 5, 6].

Another off-lattice generalisation of the HP model is the AB model [7], where the hydrophobic monomers are labelled by A and the polar or hydrophilic ones by B. The contact interaction is replaced by a more realistic distance-dependent Lennard-Jones type of potential accounting for short-range excluded volume repulsion and long-range interaction; the latter being attractive for AA and BB pairs and repulsive for AB pairs of monomers. An additional interaction accounts for the bending energy of any pair of successive bonds. This model was first applied in two dimensions [7] and generalized to three-dimensional AB proteins [8, 9], with modifications by taking implicitly into account the additional torsional energy contributions of each bond.

II. THE MODEL

In this work, we study the effective off-lattice AB model of heteropolymers with N monomers. AB model as proposed in Ref. [8] has the energy function

$$E = -\kappa_1 \sum_{k=1}^{N-2} \mathbf{b}_k \cdot \mathbf{b}_{k+1} - \kappa_2 \sum_{k=1}^{N-3} \mathbf{b}_k \cdot \mathbf{b}_{k+2} + 4 \sum_{i=1}^{N-2} \sum_{j=i+2}^{N} C(\sigma_i, \sigma_j) \left(\frac{1}{r_{ij}^{12}} - \frac{1}{r_{ij}^{6}} \right), \tag{1}$$

where $\mathbf{b}_k$ is the bond vector between the monomers k and $k+1$ with length unity. In Ref. [8] different values for the parameter set (κ_1, κ_2) were tested and finally set to $(-1, 0.5)$ as this choice provide both the distributions for the angles between bond vectors $\mathbf{b}_k$ and $\mathbf{b}_{k+1}$ and the torsion angles between the surface vectors $\mathbf{b}_k \times \mathbf{b}_{k+1}$ and $\mathbf{b}_{k+1} \times \mathbf{b}_{k+2}$ giving the best agreement with the distributions obtained for selected functional proteins. Since $\mathbf{b}_k \cdot \mathbf{b}_{k+1} = \cos \vartheta_k$, the choice $\kappa_1 = -1$ makes the coupling between successive bonds "antiferromagnetic". The second term in Eq. (1) takes torsional interactions into account. The third term contains a pure Lennard-Jones potential, where the $1/r_{ij}^6$ long-range interaction is attractive whatever types of monomers interact. The monomer-specific prefactor $C(\sigma_i, \sigma_j)$ only controls the depth of the Lennard-Jones valley:

$$C(\sigma_i, \sigma_j) = \begin{cases} +1, & \sigma_i, \sigma_j = A, \\ +1/2, & \sigma_i, \sigma_j = B \quad \text{or} \quad \sigma_i \neq \sigma_j. \end{cases} \tag{2}$$

For technical reasons, we have introduced in both models a cut-off $r_{ij} = 0.5$ for the Lennard-Jones potentials, below which the potential is repulsive hard-core (i.e., the potential is infinite).

For updating a conformation, as shown in Fig. 1, the length of the bonds are fixed ($|\mathbf{b}_k| = 1$, $k = 1, \ldots, N-1$). The $(i+1)$th monomer lies on the surface of a unit sphere centered on the ith monomer. Therefore, spherical coordinates are the natural choice for calculating the new position of the $(i+1)$th monomer on this sphere. For the reason of efficiency, all the points on the sphere are not selected for updating, but restricted the choice to a spherical cap with maximum opening angle $2\theta_{\max}$ (the dark area in Fig. 1). Thus, to change the position of the $(i+1)$th monomer to $(i+1)'$, we select the angles θ and φ randomly from the respective intervals $\cos\theta_{\max} \leq \cos\theta \leq 1$ and $0 \leq \varphi \leq 2\pi$, which ensure a uniform distribution of the $(i+1)$th monomer's positions on the associated spherical cap. After updating the position of the $(i+1)$th monomer, the following monomers in the chain are simply translated according to the corresponding bond vectors which remained unchanged in this update. This is similar to single spin updates in local-update Monte Carlo simulations of the classical Heisenberg model with the difference that, in addition to local energy changes, long-range interactions of the monomers are to be computed anew after the update,due to changing their relative position.

III. THE METHOD

The multicanonical ensemble is based on a probability function in which the different energies are equally probable. However, implementation of the multicanonical algorithm (MUCA) is not straightforward because the density of states $n(E)$ is *a priori* unknown. In practice, one only needs to know the weights ω,

$$w(E) \sim 1/n(E) = \exp[(E - F_{T(E)})/k_B T(E)], \tag{3}$$

and these weights are calculated in the first stage of simulation process by an iterative procedure in which the temperatures $T(E)$ are built recursively together with the micro-canonical free energies $F_{T(E)}/k_B T(E)$ up to an additive constant. The iterative procedure is followed by a long production run based on the fixed w's where equilibrium configurations

are sampled. Re-weighting techniques (see Ferrenberg and Swendsen [10] and literature given in their second reference) enable one to obtain Boltzmann averages of various physical variables over a wide range of temperatures.

As pointed out above, calculation of the *a priori* unknown MUCA weights is not trivial, requiring an experienced intervention. For lattice models, this problem was addressed in a sketchy way by Berg and Çelik [11] and later by Berg [12]. An alternative way is to establish an automatic process by incorporating the statistical errors within the recursion procedure.

IV. RESULTS AND DISCUSSIONS

We first carried out canonical (i.e., constant T) MC simulations of six different 20-monomer sequences [13] at temperatures $T = 0.3,\quad 0.6\quad$ and 2.4, as well as MUCA test runs to determine the required energy ranges for each sequence. The multicanonical weights were built after $m = 500$ recursions during a long *single* simulation, where the multicanonical parameters were iterated every 10000 sweeps. After having fixed the MUCA weight factors, a production run was carried out with 5×10^7 sweeps.

Fig. 2 shows, as a sample, the histograms of the multicanonical run for the sequence AAAAB-BAAAABAABAAABBA. We can see from the figure that the whole temperature range, including the hard-to-reach low-energy region, is equally well sampled. Our simulations with these multicanonical parameters reveiled the lowest energy conformation for this sequence (our suspected GEM) at $E = -59.105$.

Fig. 3 and Fig. 4 display the energy and the specific heat vs. temperature for the same sequence. The specific heat possess a peak about the temperature $T = 0.28$, which corresponds to the transition point where the system undergoes a structural change from random coil to more compact globular state.

We define an order parameter (OP) [14]

$$OP = 1 - \frac{1}{90\ n_F} \sum_{i=1}^{n_F} |\alpha_i^{(t)} - \alpha_i^{(RS)}| \ , \tag{4}$$

where n_F is the number of bond and torsion angles, $\alpha_i^{(RS)}$ and $\alpha_i^{(t)}$ are the bond and torsion angles of the considered configuration and of the choosen reference state, which is usually

taken as the global energy minimum (GEM) state. The difference $\alpha_i^{(t)} - \alpha_i^{(RS)}$ is always in the interval $[-180°, 180°]$, which in turn gives

$$-1 \leq \ < O >_T \ \leq 1 \tag{5}$$

The order parameter may be considered as a measure of coinsedence of the considered conformation with the reference state.
The free energy of the system was calculated by the formula [15]

$$F(T, OP) = E - TS(OP), \tag{6}$$

and the entropy in the above formula is,

$$S(OP) = \log H(OP) \tag{7}$$

where $H(OP)$ is the histogram that the system has an order parameter value OP at a fixed temperature T. The multicanonical algorithm provides a goal sampling of the entire energy (temperature) range and enables one to determine the histograms H without problem.

In Fig. 5, we show the free energy surface with respect to the other parameter OP and temperature T, evaluated by utilizig the multicanonical technique. The figure displays the free energy distribution of the created fifty million conformations of the choosen model protein with respect to the order parameter and temperature. Instead of potential energy, we have calculated and displayed the free energies in order to include the entropic effects, which are more meaningfull in considerations of the folding pathways. the free energy surface displays a valley structure and clearly pictures the existing funnel towards the state of global energy minimum. This topographic picture also allows one to realize at what temperature the system go through a structural change. Fig. 5, together with the contour map given in Fig. 6, enable one to visualize where the system under consideration leaves the more structural energy landscape and reaches to a funnel towards the lower energy states. This visualization is very helpfull from point of designing more effective generic simulation algoritms specific to the system under consideration.

V. CONCLUSIONS

We have simulated different 20-monomer sequences of the off-lattice AB model proteins by utilizig multicanonical ensemble approach and investigated the free energy surface. The obtained picture serves as a usefull tool for visualization of the behaviour of considered system in the configuration space and provide helpfull information in designing more effective simulation algorithms.
